Label Ranking – An Example

where the customers could be described by feature vectors, e.g., (gender, age, place of birth, has children, ...)

Label Ranking – An Example

| |  |  |  |
|---|---|--|---|
|  | 1 | 2 | 3 |
|  | 2 | 3 | 1 |
|  | 3 | 2 | 1 |
|  | ? | ? | ? |

$\pi(i)$ = position of the i -th label in the ranking

Given:

- a set of training instances $\{\mathbf{x}_1, \dots, \mathbf{x}_n\} \subseteq X$
- a set of labels $Y = \{y_1, \dots, y_m\}$
- for each training instance \mathbf{x}_k : a set of *pairwise preferences* of the form $y_i \succ_{\mathbf{x}_k} y_j$ (for some of the labels)

Find:

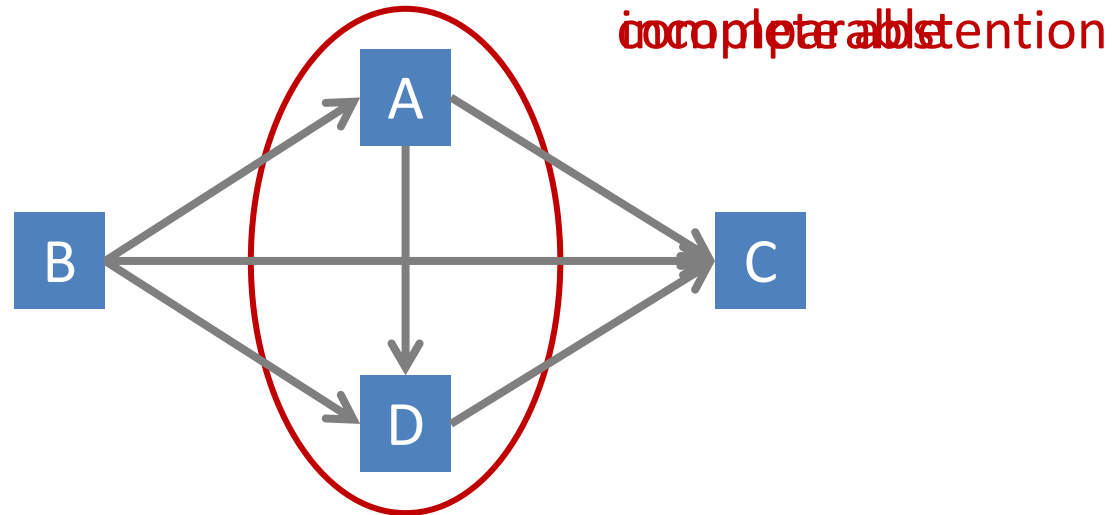

- A ranking function ($X \rightarrow \Omega$ mapping) that maps each $\mathbf{x} \in X$ to a ranking $\succ_{\mathbf{x}}$ of Y (permutation $\pi_{\mathbf{x}}$) and generalizes well in terms of a loss function on rankings

Learning with Reject Option

To train a learner that is able to say
“I don’t know”.

From Total to Partial Order Relations

Partial abstention:

The target is a total order, and a predicted partial order expresses incomplete knowledge about the target .

Partial Orders from Pairwise Comparisons

only rely on most confident comparisons → **thresholding the relation**

| | A | B | C | D |
|---|-----|-----|-----|-----|
| A | | 0.3 | 0.8 | 0.4 |
| B | 0.7 | | 0.9 | 0.7 |
| C | 0.2 | 0.1 | | 0.7 |
| D | 0.6 | 0.3 | 0.3 | |

$P(A, D)$

thresholding at 0.5

| | A | B | C | D |
|---|---|---|---|---|
| A | | 0 | 1 | 0 |
| B | 1 | | 1 | 1 |
| C | 0 | 0 | | 1 |
| D | 1 | 0 | 0 | |

Inconsistent!

Partial Orders from Pairwise Comparisons

only rely on most confident comparisons → **thresholding the relation**

| | A | B | C | D |
|---|-----|-----|-----|-----|
| A | | 0.3 | 0.8 | 0.4 |
| B | 0.7 | | 0.9 | 0.7 |
| C | 0.2 | 0.1 | | 0.7 |
| D | 0.6 | 0.3 | 0.3 | |

thresholding at 1

| | A | B | C | D |
|---|---|---|---|---|
| A | | 0 | 0 | 0 |
| B | 0 | | 0 | 0 |
| C | 0 | 0 | | 0 |
| D | 0 | 0 | 0 | |

complete abstention

Partial Orders from Pairwise Comparisons

only rely on most confident comparisons → **thresholding the relation**

| | A | B | C | D |
|---|-----|-----|-----|-----|
| A | | 0.3 | 0.8 | 0.4 |
| B | 0.7 | | 0.9 | 0.7 |
| C | 0.2 | 0.1 | | 0.7 |
| D | 0.6 | 0.3 | 0.3 | |

thresholding at 0.6

| | A | B | C | D |
|---|---|---|---|---|
| A | | 0 | 1 | 0 |
| B | 1 | | 1 | 1 |
| C | 0 | 0 | | 1 |
| D | 0 | 0 | 0 | |

Consistent, but not a partial order!

- **Problem:** Given a (valued) relation P , find the smallest threshold q such that the transitive closure of P_q defines a proper partial order.

→ **maximally informative and consistent prediction**

- There is an $O(m^3)$ algorithm for this problem, with m the number of labels [Cheng et al., ECMLPKDD2010].

Can we restrict $P(\cdot, \cdot)$ to exclude the possibility of cycles and violations of transitivity from the very beginning?

- We make use of label ranking methods that produce probability distributions \mathbf{P} over the ranking space Ω .
- We show that thresholding pairwise preferences induced by certain distributions yields partial order relations.

The Plackett-Luce Model

... is a **multistage** model specified by a vector $\mathbf{v} = (v_1, \dots, v_m) \in \mathbb{R}_+^m$:

$$\mathbf{P}(\pi \mid \mathbf{v}) = \prod_{i=1}^m \frac{v_{\pi(i)}}{v_{\pi(i)} + v_{\pi(i+1)} + \dots + v_{\pi(m)}}$$

A ranking is produced by choosing labels one by one, with a probability proportional to their respective “skills”.

The Plackett-Luce Model

$$v_{\text{green}} = 10, \quad v_{\text{red}} = 6, \quad v_{\text{blue}} = 4$$

$$P(\text{red green blue})$$

The Plackett-Luce Model

$$v_{\text{green}} = 10, \quad v_{\text{red}} = 6, \quad v_{\text{blue}} = 4$$

$$P(\text{red}, \text{green}, \text{blue}) = \frac{6}{20}$$

The Plackett-Luce Model

$$v_{\text{green}} = 10, \quad v_{\text{red}} = 6, \quad v_{\text{blue}} = 4$$

$$P(\text{red} \text{ green} \text{ blue}) = \frac{6}{20} \times \frac{10}{14}$$

The Plackett-Luce Model

$$v_{\text{green}} = 10, \quad v_{\text{red}} = 6, \quad v_{\text{blue}} = 4$$

$$\begin{aligned} \mathbf{P}(\text{red green blue}) &= \frac{6}{20} \times \frac{10}{14} \times \frac{4}{4} \\ &= \frac{3}{14} \end{aligned}$$

The Mallows Model

... is a **distance-based** model from the exponential family:

$$\mathbf{P}(\pi \mid \pi_0, \theta) = \frac{\exp(-\theta \Delta(\pi, \pi_0))}{\phi(\theta)}$$

center ranking spread normalization constant

where $\Delta(\cdot, \cdot)$ is a (right-invariant) metric on rankings.

The probability of a ranking is higher if it is close to the mode, i.e., the center ranking of the distribution.

Some Common Choices of Δ

- Kendall's tau

$$T(\pi, \sigma) = \sum_{i < j} \llbracket (\pi(i) - \pi(j)) \cdot (\sigma(i) - \sigma(j)) < 0 \rrbracket$$

- Spearman's rho

$$R(\pi, \sigma) = \sqrt{\sum_i (\pi(i) - \sigma(i))^2}$$

- Spearman's footrule

$$F(\pi, \sigma) = \sum_i |\pi(i) - \sigma(i)|$$

- Hamming

$$H(\pi, \sigma) = \sum_i \llbracket \pi(i) \neq \sigma(i) \rrbracket$$

For example:

$$\pi = (1 \ 2 \ 3 \ 4), \sigma = (1 \ 4 \ 2 \ 3)$$

$$T(\pi, \sigma) = 2$$

$$R(\pi, \sigma) = 2.45$$

$$F(\pi, \sigma) = 4$$

$$H(\pi, \sigma) = 3$$

Transposition Property

Definition A distance Δ is said to have the *transposition property* iff

$$\Delta(\pi, \sigma) \leq \Delta(\pi', \sigma)$$

for any $\pi, \sigma \in \Omega$ and i, j such that

$$\pi(i) < \pi(j) \text{ and } \sigma(i) < \sigma(j).$$

Here π' is a ranking identical to π , except for a transposition of i and j .

Kendall's tau

Spearman's rho

Spearman's footrule

Hamming

Remarks on $\mathbf{P}(y_i \succ y_j)$

$$\mathbf{P}(y_i \succ y_j) = \sum_{\pi \in \mathbf{E}(y_i, y_j)} \mathbf{P}(\pi) \rightarrow \text{linear extensions of } y_i \succ y_j$$

e.g., for $Y = \{y_1, y_2, y_3\}$, $\mathbf{E}(y_1, y_2) = \left\{ \begin{array}{l} y_1 \succ y_2 \succ y_3, \\ y_1 \succ y_3 \succ y_2, \\ y_3 \succ y_1 \succ y_2 \end{array} \right\}$.

| Model | $\mathbf{P}(y_i \succ y_j)$ |
|-----------------------------|--|
| Plackett-Luce | $\frac{v_i}{v_i + v_j}$ |
| Mallows with Spearman's rho | $\frac{1}{1 + \exp(-2\theta \cdot (\pi_0(j) - \pi_0(i)))}$ |
| Mallows with Kendall's tau | $\frac{\exp(\theta \cdot \mathbb{I}[\pi_0(j) - \pi_0(i) > 0])}{1 + \exp \theta}$ |

Our Main Result

Let the preference relation P be given by a probability distribution \mathbf{P} on Ω , that is $P(y_i, y_j) = \mathbf{P}(y_i \succ y_j)$.

Theorem Let \mathbf{P} be

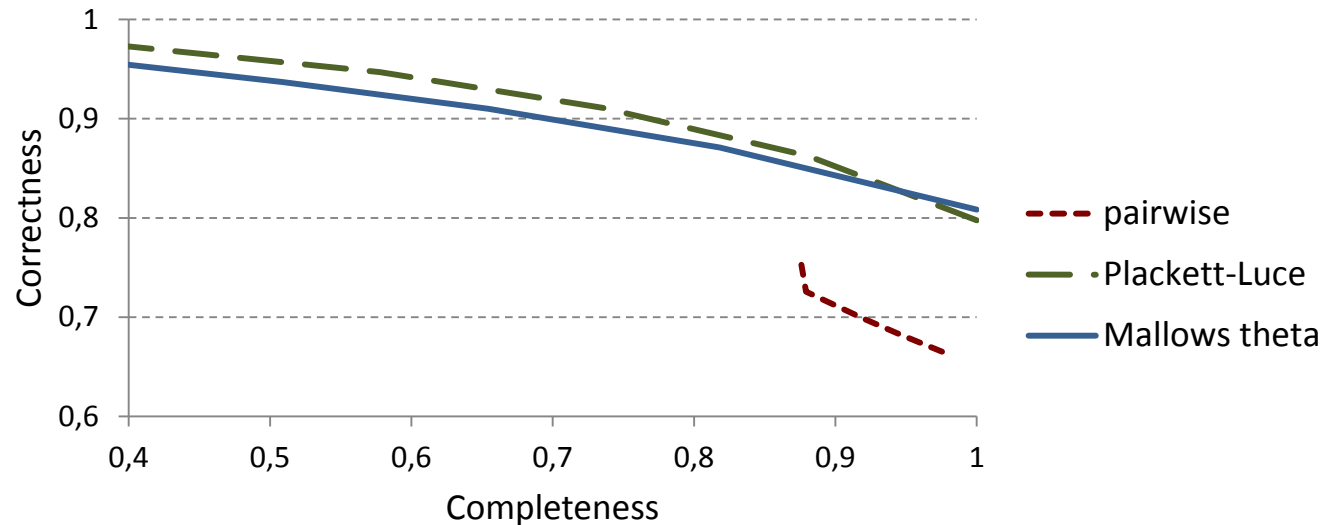

- (1) the Plackett-Luce model or
- (2) the Mallows model with a distance Δ having the transposition property.

Moreover, let Q be the thresholded relation

$$Q(y_i, y_j) = 1 \text{ if } P(y_i, y_j) > q \text{ and}$$
$$Q(y_i, y_j) = 0 \text{ otherwise.}$$

Then Q defines a proper partial order relation for all $q \in [1/2, 1)$.

Experimental Results

- Results on the UCI benchmark data set VOWEL;
- Correctness (measured by gamma rank correlation):

$$\frac{|\text{concordant pairs}| - |\text{discordant pairs}|}{|\text{concordant pairs}| + |\text{discordant pairs}|}$$

- Completeness: 1 – the relative number of pairwise comparisons on which the model abstains.

- A natural way to derive partial orders is via **thresholding** a (valued) binary **preference relation**.
- While this may yield inconsistencies in general, we have shown that proper partial orders are produced when restricting to preference relations induced by specific types of **probability distributions on rankings**.
- This approach is not only theoretically sound, but also performs well in **experimental studies**.
- While our focus was **on label ranking**, the results immediately apply to other ranking problems, too.

Label Ranking with Abstention

Predicting Partial Orders by Thresholding Probability Distributions
